ABSTRACT

This supplement reports the complete locked specification registry, detailed source-native gates, all primary specification outcomes, all familywise decisions, cross-feed results, timestamp-alignment sensitivity, deflated-Sharpe diagnostics, protocol deviations, audit scope, and evidence map. Machine-readable versions of all reported tables accompany the submission package.

S1. Registry construction and status labels

The registry was frozen before consolidated specification outcome computation. Every row identifies the source block, source candidate, economic family, analysis role, direction, horizon, reference interval, alignment and cross-feed requirements, source-code digest, configuration digest, and serialized signal contract. The registry-set SHA-256 is e20d26b5fe2fe6db25a8cdf48cf8650b1b726be0a78c500549e51e11522b8a07.

The 39 rows labeled PRIMARY_LOCKED_RERUN form the article’s primary universe. The 8 machine-learning rows are labeled HISTORICAL_FORENSIC_CASE_STUDY_ONLY; they were historically selected and had been exposed to later diagnostic information. They were intentionally not rerun and do not enter any primary result.

Table 1: Complete locked registry.

S2. Data contract and source bindings

The primary intraday contract is 2015-01-02 07:00 UTC through, but not including, 2025-01-01 00:00 UTC. Cross-asset fixed and event-response blocks begin on 2016-01-01. The relative-value rule begins on 2012-01-01 and requires a 252-session formation sample. The monthly trend rule begins after a 12-month return lookback and a minimum of 120 past daily returns.

AMarkets server timestamps are converted under `EU_DST_GMT_OFFSET_PAIR`: subtract 120 minutes during standard time and 180 minutes during European daylight-saving time. The data-contract preflight recorded zero duplicate timestamps and zero invalid OHLC rows. The input hashes required for independent source comparison are:

- AMarkets alignment SQLite: c38491993ec5b76325d61f941cbddf7cda7147c83c97f43b80e97221385669f5.
- Dukascopy extended-history SQLite: 8d9a3f9d7e8a05cc9fa97badd93aa809e1c09b105eacb3b96720671aa74c66de.
- Frozen timestamp contract: 635ed1f9cd9ec62fecdff61e3e9660657194d972e4f4f889731e97d1432ea362.
- Official-event timestamps: 601f587e0128d4322bc3ea5071545e53adf035b5e08fdbafa72cf16a550ec560.

The complete additional input bindings are recorded in the frozen main-run manifest retained with the evidence package. Raw provider data are not included in this journal package.

S3. Exact strategy-class contracts

S3.1. Successor price-only rules

Nineteen non-overlapping rules cover ten families: trend continuation, trend pullback, range breakout, volatility expansion, session breakout, post-event momentum, post-event breakout, failed-breakout reversion, low-volatility range reversion, and *z*-score reversion. The registry supplies each fixed direction, horizon, threshold, and signal contract. The reference interval is 2015-01-02 07:00 UTC to 2025-01-01 00:00 UTC exclusive.

S3.2. Cross-asset fixed rules

The 12 rules form six economic families with 4- or 12-hour horizons. Decisions occur during 06:00–19:00 UTC on weekdays and exclude official-event blackout periods. Standardized features use a 1,440-row rolling window and at least 480 past observations. Signals within a candidate are non-overlapping.

S3.3. Event-response rules

The six rules use 4- or 12-hour horizons and enter only when an official event occurred 15–120 minutes before the decision. The official-event file is hash-bound. Standardized 15-minute reactions in XAUUSD, XAGUSD, and the dollar composite determine the locked directional conditions.

S3.4. Time-series momentum

The sign of the prior 12 completed monthly returns determines a long or short position for one month. Volatility is estimated from past daily returns using a 60-day exponentially weighted center of mass and 261-day annualization. The annual volatility target is 20%, absolute position is capped at 2.0, and turnover is charged on the complete monthly position change. The comparison benchmark is passive volatility-scaled long gold under the same risk and cost model.

S3.5. Gold-silver relative value

The rule estimates $\log(XAU) = \alpha + \beta \log(XAG)$ over 252 completed daily closes. It enters at the next synchronized open after $|z| \geq 2$, exits at the next open following a mean crossing, adverse $|z| \geq 4$, or 60-day maximum holding, and uses gross-normalized fixed entry weights. The rule is not a parameter scan; structural-break and cointegration quantities are diagnostic only.

S4. Cost formulas and source-native gates

For each directional trade, gross basis-point return is $10,000s(P_{out}/P_{in} - 1)$. Source-specific net returns subtract the applicable round-trip or turnover cost. Severe costs are primary. Fixed stress is a secondary comparison: 10 bps for one-leg intraday rules and each unit of monthly turnover, and 20 bps for the two-leg rule.

Table 2: Source-native reference gates.

Block	Complete conjunction
Successor scan	At least 40 trades; severe mean > 0 ; profit factor ≥ 1.15 ; block-bootstrap 10th percentile > 0 ; positive mean after removing the largest winner; positive-fold share ≥ 0.60 ; locked-risk CAGR $\geq 2\%$.
Cross-asset fixed	At least 80 trades; severe mean > 0 ; profit factor ≥ 1.20 ; bootstrap 10th percentile > 0 ; positive after removing the largest winner; matched year/hour excess mean and bootstrap lower bound > 0 ; at least 2 of 3 positive folds; worst-fold mean ≥ -5 bps; maximum positive-year profit share $\leq 45\%$; locked-risk CAGR $\geq 2\%$.
Event response	At least 40 trades; severe mean > 0 ; profit factor ≥ 1.20 ; bootstrap 10th percentile > 0 ; positive after removing the largest winner; matched excess mean and lower bound > 0 ; at least 2 of 3 positive folds; worst-fold mean ≥ -5 bps; maximum positive-year profit share $\leq 50\%$; locked-risk CAGR $\geq 1\%$.
Canonical TSMOM	At least 120 months; severe annualized return $> 2\%$; Sharpe > 0.20 ; moving-block bootstrap 10th-percentile monthly mean > 0 ; annualized return after removing best month > 0 ; at least 2 of 3 positive folds; worst-fold annualized return $> -10\%$; positive-year share $\geq 55\%$; positive-year concentration $\leq 50\%$; maximum drawdown $\leq 50\%$; paired excess mean and bootstrap lower bound versus passive volatility-scaled gold > 0 .

Block	Complete conjunction
Precious-metals RV	At least 25 trades; severe mean > 0 ; profit factor ≥ 1.20 ; bootstrap lower bound and remove-best-trade mean > 0 ; annualized return $\geq 2\%$; maximum drawdown $\leq 25\%$; at least 2 positive folds; worst-fold annualized return $\geq -5\%$; positive-year share $\geq 45\%$; year concentration $\leq 50\%$; trade concentration $\leq 25\%$; mean better than the inverted rule; random-side percentile ≥ 0.90 .

S5. Complete primary specification results

Table 3 contains all primary rows. The adjusted probability is the specification-level value obtained from the relevant within-family max- t distribution. The family decision uses the family maximum and is reported in Section S6.

Table 3: Complete primary specification results. Returns are mean basis points per native trade or rebalance.

S6. Complete familywise decisions

All family tests use centered, synchronized, circular moving blocks of 20 calendar days, 5,000 replications, and seed 2026090201. Severe-cost returns are assigned to the UTC exit date and inactive dates receive zero. All 20 final decisions are NO_EDGE_UNDER_LOCKED_PROTOCOL.

S7. Cross-feed replication

Replication is applicable to 19 successor rules and the canonical trend rule. Passing requires at least 30 matched outcomes, signal Jaccard similarity ≥ 0.60 , matched gross-return correlation ≥ 0.90 , and consistent severe-cost effect direction. Five failures are Jaccard failures and two are sign reversals.

Table 5: Complete cross-feed results for eligible specifications.

ID	Primary N	Secondary N	Jaccard	Return corr.	Secondary severe	Pass
A1R-001	3476	3546	0.633	0.999	-5.186	Yes

S9. Deflated Sharpe ratios and PBO status

The DSR uses a common daily calendar from 2016-01-01 through 2024-12-31, 365-day annualization, 39 eligible trials, and a 0.95 reporting threshold. The expected maximum daily Sharpe is 0.0477359441. No specification passes.

Table 7: Complete deflated-Sharpe diagnostic.

ID	Daily Sharpe	Annualized	Skewness	Kurtosis	DSR probability	Pass
A1R-001	-0.0782	-1.495	0.011	14.682	0.00000	No

A1R-046	-0.0046	-0.088	0.174	98.651	0.00136	No
A1R-047	-0.0053	-0.102	3.422	318.589	0.00130	No

PBO is not estimable because the universe does not form a valid combinatorially symmetric cross-validation matrix: event-only, intraday, monthly, and two-leg strategies have heterogeneous calendars, holding horizons, and objectives. No substitute scalar was computed after the outcome.

S10. Protocol deviations

A1-DEV-001. The redacted evidence copy of the canonical trend script had a different digest. Independent package evidence established that three malformed redaction placeholders in authorization and decision-reporting statements had been restored. No signal-generation or performance-computation statement changed. The registry was reissued as version 1.1 before the consolidated rerun.

A1-DEV-002. The first unified run requested the Dukascopy H1 table from the AMarkets SQLite file and aborted before entering any specification-outcome loop. Version 1.1 routed the AMarkets and Dukascopy tables to their already hash-bound databases and added schema gates. No strategy, cost, statistic, or seed changed. The aborted directory was retained.

S11. Independent audit boundary

The independent audit verified safe archive paths, no duplicate members, CRC integrity, manifest completeness, file byte sizes and hashes, lock hashes, registry identities, outcome-table uniqueness, reference boundaries, finite returns, and the 28,685-row count. It independently recomputed each specification's count, four mean-return layers, severe-cost profit factor, all family max- t results, and all DSR probabilities.

The audit did not regenerate every signal and trade from raw broker/vendor databases. It is therefore an output-level statistical reproduction with strong provenance checks, not a complete independent raw-data replication.

S12. Evidence ledger

Table 8: Central claim-to-artifact map.

Claim	Authoritative file	Field or check
47 registered; 39 primary; 8 forensic-only	article1_reference_rerun_summary.json	Registry counts
20 families; none supported	family_reference_decisions.csv	decision
28,685 normalized rows	all_primary_reference_trades.csv.gz	Independent row count
Positive counts 24/9/5/1	specification_reference_metrics.csv	Four mean-return columns

Claim	Authoritative file	Field or check
No native pass	specification_reference_metrics.csv	source_native_pass
Minimum family $p = 0.446111$	family_reference_decisions.csv	family_adjusted_p
Cross-feed: 13 pass, 7 fail	cross_feed_replication.csv	Applicability and checks
No alignment fragility	alignment_warning_sensitivity.csv	Sign/pass changes
Maximum DSR probability 0.011284	deflated_sharpe_ratio.csv	DSR probability
PBO not estimable	evaluation_protocol.json	Status and reason
Audit passed with limitations	independent_audit_report.json	Integrity and recomputation

S13. Reproduction instructions

Run `python3 build_figures.py` in a directory containing the supplied CSV files to reproduce all figures and generated LaTeX tables. Compile each TeX entry point with `latexmk -pdf`. The article-level package contains the CAS single-column class and bibliography style at the same directory level because Elsevier's Editorial Manager does not process nested LaTeX source folders.
